

Python Boolean Operations

Controlling Logic with `and`, `or`, and `not`

1. `and` Operator (Series Circuit)

Result is **True** only if BOTH inputs are **True**.

A=**True**, B=**True** -> Light ON

A=**True**, B=**False** -> Light OFF

```
permit = True
materials = True
can_build = permit and materials
print(can_build) # True
```

2. `or` Operator (Parallel Circuit)

Result is **True** if AT LEAST ONE input is **True**.

A=**True**, B=**False** -> Light ON

A=**False**, B=**False** -> Light OFF

```
window = True
skylight = False
daylight = window or skylight
print(daylight) # True
```

3. `not` Operator (Inverter)

Inverts the boolean value. **True** becomes **False**.

Input -> NOT -> Output

```
is_load_bearing = False
can_demolish = not is_load_bearing
print(can_demolish) # True
```
