

Boolean (bool)

Only two objects exist: 'True' and 'False'.
Variables just point to one of them. Memory usage is fixed and small.

Integer (int)

Memory grows as the number gets larger. Starts with a base overhead for the object information.

Float (float)

Usually a fixed size (64-bit precision), regardless of the value, as it follows a standard format.

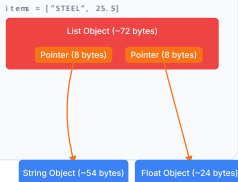

String (str)

Base overhead plus memory for each character.
Longer strings use significantly more memory.

List (list)

The list itself holds pointers (references) to other objects in memory, not the objects themselves.

Dictionary (dict)

A complex structure with significant overhead for fast lookups. Has empty slots to remain efficient.
