

Anatomy of a Python Function

A Reusable machine for your code

1. Inputs (Parameters)

Data you provide to the function.

```
width = 10.5  
depth = 20.0
```

Values are
passed in

2. The Function (Process)

A named block of code that
performs a specific task.

Internal Calculation:

```
area = width * depth  
return area
```

A value is
returned

3. Output (Return Value)

The result the function sends back.

```
room_area = 210.0
```

Complete code example

```
def calculate_area(width, depth):  
    # Takes width and depth as parameters    # Calling the function with arguments  
    area = width * depth  
    return area # Returns the calculated areaprint(room_area) # Output: 210.0  
  
room_area = calculate_area(10.5, 20.0)
```
