

A loop and a vectorized expression can describe the same transformation

Element-by-element loop

```
results = []  
for value in values:  
    results.append(value * 1.1)
```

Python coordinates each iteration.

NumPy vectorized expression

```
results = values * 1.1
```

```
[10, 20, 30] -> [11, 22, 33]
```

The array operation states the transformation directly.
